

# Progress

# Data Observations

- Domain Knowledge
- Downscale Dataset
- Running Visuals

# Using Keras

We decided to use Keras due to its ease of use but also its flexibility

Implemented a relatively basic neural net. Two layers, 64 nodes.

We have experimented with adding custom metrics, because one of the big targets is reducing the number of false positives. This had to be custom implemented to specifically consider any “benign” data that is misidentified as any of the malware types.

# Future Direction

- Finish testing
- Fine tune current model
  - Tweak the data included in the model
  - Calculate number of false positives
- Research and implement alternative models
  - Recurrent Neural Network
